

Amendments to the Claims:

This listing of claims will replace all prior versions, and listings, of the claims in the application:

Listing of Claims:

1. (original) A method comprising:
combining at least two separate user information packets into a transmission packet by an information-processing unit; and
eliminating at least one power up cycle and one power down cycle by transmitting the transmission packet.
2. (original) The method of claim 1, wherein a total elapsed time between the at least two separate user information packets is greater than a portion of a system quality of service (QoS) parameter allocated to the information-processing unit.
3. (original) The method of claim 1, wherein a total elapsed time between the at least two separate user information packets is less than a portion of a system quality of service (QoS) parameter allocated to the information-processing unit.
4. (original) The method of claim 1, wherein a total elapsed time between the at least two separate user information packets is equal to a portion of a system quality of service (QoS) parameter allocated to the information-processing unit.
5. (original) The method of claim 1, wherein an end-to-end quality of service (QoS) requirement is maintained during said combining.
6. (original) The method of claim 1, wherein information contained in the user information packets are at least one of packet voice and packet data.
7. (original) An apparatus comprising:

an information-processing unit to combine at least two separate user information packets into a transmission packet;

wherein at least one power up cycle and one power down cycle is eliminated.

8. (original) The apparatus of claim 7, wherein information contained in the user information packets are at least one of packet voice and packet data.

9. (previously presented) An apparatus comprising:

a signal embodied in a propagation medium,

wherein said signal represents the combination of at least two separate user information packets combined into a single transmission packet by an information-processing unit to eliminate at least one power up cycle and one power down cycle.

10. (original) The apparatus of claim 9, wherein an end-to-end quality of service (QoS) requirement is maintained during the combination of the at least two separate user information packets.

11. (original) The apparatus of claim 9, wherein a total elapsed time between the at least two separate user information packets is greater than a portion of a system quality of service (QoS) parameter allocated to an information-processing unit.

12. (original) The apparatus of claim 9, wherein a total elapsed time between the at least two separate user information packets is less than a portion of a system quality of service (QoS) parameter allocated to an information-processing unit.

13. (original) The apparatus of claim 9, wherein a total elapsed time between the at least two separate user information packets is equal to a portion of a system quality of service (QoS) parameter allocated to an information-processing unit.

14. (previously presented) A method comprising:

grouping at least two separate user information packets;

combining the least two separate user information packets into a single transmission packet by an information-processing unit; and
eliminating at least one power up cycle and one power down cycle by transmitting the transmission packet.

15. (original) The method of claim 14, wherein a total elapsed time between the at least two separate user information packets is greater than a portion of a system quality of service parameter (QoS) allocated to the information-processing unit.

16. (original) The method of claim 14, wherein a total elapsed time between the at least two separate user information packets is less than a portion of a system quality of service parameter (QoS) allocated to the information-processing unit.

17. (original) The method of claim 14, wherein a total elapsed time between the at least two separate user information packets is equal to a portion of a system quality of service parameter (QoS) allocated to the information-processing unit.

18. (original) The method of claim 14, wherein information contained in the user information packets are at least one of packet voice and packet data.

19. (original) The method of claim 14, wherein an end-to-end quality of service (QoS) requirement is maintained.

20. (previously presented) The method of claim 14, wherein a portion of a system quality of service parameter (QoS) allocated to the information-processing unit is dynamically changed.

21. (currently amended) An apparatus comprising:
an information-processing unit to combine at least two separate user information packets into a single transmission packet and to eliminate at least one power up cycle and one power down cycle by transmitting the single transmission packet.

22. (original) The apparatus of claim 21, wherein a total elapsed time between the at least two separate user information packets is greater than a portion of a system quality of service parameter (QoS) allocated to the information-processing unit.

23. (original) The apparatus of claim 21, wherein a total elapsed time between the at least two separate user information packets is less than a portion of a system quality of service parameter (QoS) allocated to the information-processing unit.

24. (original) The apparatus of claim 21, wherein a total elapsed time between the at least two separate user information packets is equal to a portion of a system quality of service parameter (QoS) allocated to the information-processing unit.

25. (previously presented) The apparatus of claim 21, wherein an end-to-end quality of service (QoS) requirement is maintained.

26. (original) The apparatus of claim 21, wherein information contained in the user information packets are at least one of packet voice and packet data.

27. (previously presented) A computer readable medium containing executable program instructions, which when executed by a data processing system, cause the data processing system to perform the steps comprising:

combining at least two separate user information packets into a single transmission packet by an information-processing unit; and

eliminating at least one power up cycle and one power down cycle by transmitting the transmission packet.

28. (original) The computer readable medium of claim 27, wherein a total elapsed time between the at least two separate user information packets is greater than a portion of a system quality of service parameter (QoS) allocated to the information-processing unit.

29. (original) The computer readable media of claim 27, wherein a total elapsed time between the at least two separate user information packets is less than a portion of a system quality of service parameter (QoS) allocated to the information-processing unit.

30. (original) The computer readable media of claim 27, wherein a total elapsed time between the at least two separate user information packets is equal to a portion of a system quality of service parameter (QoS) allocated to the information-processing unit.

31. (original) The computer readable media of claim 27, wherein an end-to-end quality of service (QoS) requirement is maintained.

32. (previously presented) A method comprising:

inputting a single transmission packet of user information comprising a combination of at least two separate user information packets into an information transmission system;

conveying the transmission packet through the information transmission system;

and

eliminating at least one power up cycle and one power down cycle by conveying the transmission packet.

33. (original) The method of claim 32, wherein a total elapsed time between the at least two separate user information packets is greater than a portion of a system quality of service (QoS) parameter allocated to an information-processing unit.

34. (original) The method of claim 32, wherein the total elapsed time between the at least two separate user information packets is less than the portion of the system quality of service (QoS) parameter allocated to an information-processing unit.

35. (original) The method of claim 32, wherein the total elapsed time between the at least two separate user information packets is equal to the portion of the system quality of service (QoS) parameter allocated to an information-processing unit.

36. (original) The method of claim 32, wherein information contained in the user information packets are at least one of packet voice and packet data.

37. (original) The method of claim 32, wherein the quality of service (QoS) parameter for the information transmission system is maintained.

38. (original) The method of claim 32, wherein an end-to-end quality of service (QoS) requirement is maintained.

39. (previously presented) The method of claim 32, wherein a portion of a system quality of service parameter (QoS) allocated to the information-processing unit is dynamically changed.

40. (previously presented) An apparatus comprising:
an information transmission system to receive and convey a single transmission packet of user information comprising at least two separate user information packets,
wherein at least one power up cycle and one power down cycle is eliminated by conveying the single transmission packet.

41. (original) The apparatus of claim 40, wherein a total elapsed time between the at least two separate user information packets is greater than a portion of a system quality of service (QoS) parameter allocated to an information-processing unit.

42. (original) The apparatus of claim 40, wherein the total elapsed time between the at least two separate user information packets is less than the portion of the system quality of service (QoS) parameter allocated to the information-processing unit.

43. (original) The apparatus of claim 40, wherein the total elapsed time between the at least two separate user information packets is equal to the portion of the system quality of service (QoS) parameter allocated to the information-processing unit.

44. (original) The apparatus of claim 40, wherein information contained in the user information packets are at least one of packet voice and packet data.

45. (original) The apparatus of claim 40, wherein an end-to-end quality of service (QoS) requirement is maintained.

46. (previously presented) A computer readable medium containing executable program instructions, which when executed by a data processing system, cause the data processing system to perform a method comprising:

inputting a single transmission packet of user information comprising a combination of at least two separate user information packets into an information transmission system; ~~and~~

conveying the transmission packet through the information transmission system;
and

eliminating at least one power up cycle and one power down cycle by conveying the transmission packet.

47. (original) The computer readable medium of claim 46, wherein a total elapsed time between the at least two separate user information packets is greater than a portion of a system quality of service (QoS) parameter allocated to an information-processing unit.

48. (original) The computer readable medium of claim 46, wherein a total elapsed time between the at least two separate user information packets is less than a portion of a system quality of service (QoS) parameter allocated to an information-processing unit.

49. (original) The computer readable medium of claim 46, wherein a total elapsed time between the at least two separate user information packets is equal to a portion of a system quality of service (QoS) parameter allocated to an information-processing unit.

50. (previously presented) A method comprising:

receiving, from an information transmission system, a single transmission packet of user information, comprising a combination of at least two separate user information packets, into an information-processing unit;

processing at least one of the transmission packet and the at least two separate user information packets; and

eliminating at least one power up cycle and one power down cycle by processing the at least one transmission packet.

51. (original) The method of claim 50, wherein a total elapsed time between the at least two separate user information packets is greater than a portion of a system quality of service parameter (QoS) allocated to an information-processing unit that formed the transmission packet.

52. (original) The method of claim 50, wherein a total elapsed time between the at least two separate user information packets is less than a portion of a system quality of service parameter (QoS) allocated to an information-processing unit that formed the transmission packet.

53. (original) The method of claim 50, wherein a total elapsed time between the at least two separate user information packets is equal to a portion of a system quality of service parameter (QoS) allocated to an information-processing unit that formed the transmission packet.

54. (original) The method of claim 50, wherein information contained in the user information packets are at least one of packet voice and packet data.

55. (original) The method of claim 50, wherein an end-to-end QoS requirement is maintained.

56. (previously presented) A computer readable medium containing executable program instructions, which when executed by a data processing system, cause the data processing system to perform a method comprising:

receiving, from an information transmission system, a single transmission packet of user information, comprising a combination of at least two separate user information packets, into an information-processing unit;

processing at least one of the transmission packet and the at least two separate user information packets; and

eliminating at least one power up cycle and one power down cycle by processing the at least one transmission packet.

57. (original) The computer readable medium of claim 56, wherein a total elapsed time between the at least two separate user information packets is greater than a portion of a system quality of service parameter allocated to an information-processing unit that formed the transmission packet.

58. (original) The computer readable medium of claim 56, wherein a total elapsed time between the at least two separate user information packets is less than a portion of a system quality of service parameter allocated to an information-processing unit that formed the transmission packet.

59. (original) The computer readable medium of claim 56, wherein a total elapsed time between the at least two separate user information packets is not equal to a portion of a system quality of service parameter allocated to an information-processing unit that formed the transmission packet.

60. (previously presented) The method of claim 50, wherein a portion of a system quality of service parameter (QoS) allocated to the information-processing unit is dynamically changed.

61. (original) A computer readable medium containing executable program instructions, which when executed by a data processing system, cause the data processing system to perform the steps comprising:

combining at least two separate user information packets into a transmission packet by an information-processing unit; and

eliminating at least one power up cycle and one power down cycle by transmitting the transmission packet.

62. (original) The computer readable medium of claim 61, wherein a total elapsed time between the at least two separate user information packets is greater than a portion of a system quality of service (QoS) parameter allocated to the information-processing unit.

63. (original) The computer readable medium of claim 61, wherein a total elapsed time between the at least two separate user information packets is less than a portion of a system quality of service (QoS) parameter allocated to the information-processing unit.

64. (original) The computer readable medium of claim 61, wherein a total elapsed time between the at least two separate user information packets is equal to a portion of a system quality of service (QoS) parameter allocated to the information-processing unit.
